**Abstract.** In the trivial  $n$ -recipient public-key encryption scheme, a ciphertext is a concatenation of independently encrypted messages for  $n$  recipients. In this paper, we say that an  $n$ -recipient scheme has a “*shortened ciphertext*” property if the length of the ciphertext is almost a half (or less) of the trivial scheme and the security is still almost the same as the underlying single-recipient scheme. We first present (multi-plaintext, multi-recipient) schemes with the “*shortened ciphertext*” property for ElGamal scheme and Cramer-Shoup scheme. We next show (single-plaintext, multi-recipient) hybrid encryption schemes with the “*shortened ciphertext*” property.

**Keywords:** public-key encryption, multi-recipient setting, ElGamal, Cramer-Shoup, hybrid encryption, concrete security.

## 1 Introduction

### 1.1 Background

Suppose that there are  $n$  recipients. Let  $pk_i$  be the public key of recipient  $i$  for  $1 \leq i \leq n$ . The security of a public-key encryption scheme in the multi-recipient setting is different from the single-recipient setting. For example, if  $e$  is the common public exponent in RSA, then  $e$  encryptions of the same plaintext  $M$  under different moduli lead to an easy recovery of  $M$ . Further

results by Hastad [11] and Coppersmith [7, 8] proved that even the time-stamp variants can be successfully attacked with  $e$  ciphertexts.

In the trivial  $n$ -recipient public-key encryption scheme, a ciphertext is just a concatenation of independently encrypted messages for  $n$  recipients using a single-recipient public-key encryption algorithm  $\mathcal{E}$ . That is,  $\mathcal{E}_{pk_1}(M_1) || \cdots || \mathcal{E}_{pk_n}(M_n)$ , where  $||$  denotes concatenation. In general, this trivial scheme is not secure in the sense of invertibility even if  $\mathcal{E}$  is secure in the same sense, as shown in the above RSA example.

Recently, Bellare et al. [2] and Baudron et al. [1] independently proved that the trivial  $n$ -recipient scheme is secure in the sense of indistinguishability [10] if  $\mathcal{E}$  is secure in the same sense, where indistinguishability is a stronger security notion than invertibility.

However, their nice results [2, 1] still do not capture the essence of the multi-recipient setting:

- (1) The length of the ciphertext of the trivial  $n$ -recipient scheme is  $n$  times larger than that of the underlying single-recipient scheme.
- (2) Consider a single-recipient hybrid encryption scheme which encrypts a long message  $M$  using a pseudorandom generator  $G$  and sends the seed  $r$  of  $G$  using a public-encryption scheme. That is,

$$C = M \oplus G(r) || \mathcal{E}_{pk}(r), \quad (1)$$

where  $||$  denotes concatenation. A natural extension of the hybrid scheme to an  $n$ -recipient scheme will be that

$$M \oplus G(r) || \mathcal{E}_{pk_1}(r) || \cdots || \mathcal{E}_{pk_n}(r). \quad (2)$$

Their results [2, 1] only imply that the latter part  $\mathcal{E}_{pk_1}(r) || \cdots || \mathcal{E}_{pk_n}(r)$  is secure in the sense of indistinguishability if the single-recipient part  $\mathcal{E}_{pk}(r)$  is secure in the same sense.

## 1.2 Our Contribution

In this paper, we consider  $n$ -recipient public-key encryption schemes such that the length of the ciphertext is almost a half (or less) of the trivial  $n$ -recipient scheme and the security is still almost the same as the underlying single-recipient scheme. We say that such a scheme has a “*shortened ciphertext*” property.

1. We first give the definitions of our model and the security.

2. We next present (*multi*-plaintext, multi-recipient) schemes with the “*shortened ciphertext*” property for ElGamal scheme and Cramer-Shoup scheme and prove their security.
3. We also prove that the above mentioned (*single*-plaintext, multi-recipient) scheme of eq.(2) is secure in the sense of indistinguishability against chosen plaintext attack if the underlying single-recipient public-key scheme is secure in the same sense.
4. We finally present how to construct a (single-plaintext, multi-recipient) scheme secure against chosen *ciphertext* attack with the “shortened ciphertext” property. The underlying single-recipient public-key scheme needs to be secure in the sense of indistinguishability against chosen ciphertext attack. (For example, we can use Rabin-SAEP or RSA-SAEP<sup>+</sup> [4] as the underlying single-recipient scheme.)

Cramer-Shoup scheme is a practical public-key encryption scheme which is secure in the sense of indistinguishability against chosen-ciphertext attack under the decision Diffie-Hellman (DDH) assumption in the standard model [9]. The basic Cramer-Shoup scheme uses universal one-way hash functions (UOH) [9, Sec.3]. Bellare et al. derived the concrete security of the basic Cramer-Shoup scheme by assuming the concrete security of UOH [2]. On the other hand, Cramer and Shoup also presented a hash-free variant which does not use UOH [9, Sec.5.3].

We derive the concrete security of the hash-free variant of Cramer-Shoup scheme. It is of independent interest because it truly depends only on the DDH assumption, but not UOH. We then present a (multi-plaintext, multi-recipient) hash-free Cramer-Shoup scheme that has the “*shortened ciphertext*” property.

One further advantage of our multi-recipient schemes (in the discrete log setting) is that the encryption operation can be significantly faster than if the encryption operations were performed separately for each recipient.

Finally, in all of our multi-recipient schemes, the decryption algorithm is the same as the single-recipient one. Therefore, no extra cost is required for each recipient.

### 1.3 Related Works

The “broadcast” problem has been addressed by other authors in the context of traitor-tracing [6, 12, 5, 13]. The traitor-tracing schemes such that [12, 5,

13] can have even shorter ciphertexts than our schemes, but with the tradeoff that a small coalition of recipients can break the traitor-tracing aspect of the scheme, i.e., construct a new private key that does not identify anyone in the coalition. In our schemes, no coalition can do this since each private key uniquely identifies the recipient.

Bellare and Rogaway [3] proved that the single recipient hybrid encryption scheme shown in eq.(1) is secure in the sense of indistinguishability against chosen plaintext attack under the random oracle model if  $\mathcal{E}_{pk}$  is a trapdoor oneway permutation. They also proved that the following scheme is secure in the sense of indistinguishability against chosen ciphertext attack under the random oracle model.

$$C = \mathcal{E}_{pk}(r) || M \oplus G(r) || H(M || r),$$

where  $H$  is a hash function. Before that, Zheng and Seberry [16] proposed a scheme such that

$$C = \mathcal{E}_{pk}(r) || (G(r) \oplus (M || H(M))).$$

## 2 Single-Recipient Encryption Scheme

A single-recipient public-key encryption scheme  $\mathcal{PE} = (\mathcal{K}, \mathcal{E}, \mathcal{D})$  consists of three algorithms. The key generation algorithm  $\mathcal{K}$  outputs  $(pk, sk)$  on input some global information  $I$ , where  $pk$  is a public key and  $sk$  is the secret key; we write  $(pk, sk) \xleftarrow{R} \mathcal{K}(I)$ . The encryption algorithm  $\mathcal{E}$  outputs a ciphertext  $C$  on input the public key  $pk$  and a plaintext  $M$ ; we write  $C \xleftarrow{R} \mathcal{E}_{pk}(M)$ . The decryption algorithm  $\mathcal{D}$  outputs  $M$  or *reject* on input the secret key  $sk$  and a ciphertext  $C$ ; we write  $x \leftarrow \mathcal{D}_{sk}(C)$ , where  $x = M$  or *reject*. We require that  $\mathcal{D}_{sk}(\mathcal{E}_{pk}(M)) = M$  for each plaintext  $M$ .

An adversary  $B$  runs in two stages. In “find” stage, it takes a public key  $pk$  and outputs two equal length messages  $M_0$  and  $M_1$  together with some state information *state*. In “guess” stage, it gets a challenge ciphertext  $C_b \xleftarrow{R} \mathcal{E}_{pk}(M_b)$  from the encryption oracle  $\mathcal{E}_{pk}$ , where  $b$  is a randomly chosen bit.  $B$  finally outputs a bit  $\tilde{b}$ . The advantage of  $B$  is measured by the probability  $\Pr(\tilde{b} = b)$ .

Formally, the security of  $\mathcal{PE}$  in the sense of indistinguishability against chosen-plaintext attack is defined as follows.

**Definition 2.1** For  $b = 0$  and  $1$ , define the experiment as follows.

$$(pk_1, sk_1) \xleftarrow{R} K(I), (M_0, M_1, state) \xleftarrow{R} B(find, pk), C_b \xleftarrow{R} \mathcal{E}_{pk}(M_b), \tilde{b} \xleftarrow{R} B(guess, C_b, state).$$

Let

$$\begin{aligned} \text{Adv}_{\mathcal{PE}, I}^{\text{s-cpa}}(B) &\stackrel{\text{def}}{=} \Pr(\tilde{b} = 0 \mid b = 0) - \Pr(\tilde{b} = 0 \mid b = 1) \\ \text{Adv}_{\mathcal{PE}, I}^{\text{s-cpa}}(t) &\stackrel{\text{def}}{=} \max_B \text{Adv}_{\mathcal{PE}, I}^{\text{s-cpa}}(B), \end{aligned}$$

where the maximum is over all  $B$  with time-complexity  $t$ .

(In the superscript,  $s$ - denotes "single recipient".)

**Definition 2.2** We say that  $\mathcal{PE}$  is secure against chosen-plaintext attack if  $\text{Adv}_{\mathcal{PE}, I}^{\text{s-cpa}}(t)$  is negligible for polynomially bounded  $t$ , where the complexity is measured as a function of a security parameter.

It is easy to see that

$$\Pr(\tilde{b} = b) = \frac{1}{2} + \frac{1}{2} \text{Adv}_{\mathcal{PE}, I}^{\text{s-cpa}}(B) \quad (3)$$

The security against chosen-ciphertext attack is defined similarly except for that the adversary  $B$  gets the decryption oracle  $\mathcal{D}_{sk}$  and is allowed to query any ciphertext  $C$  at most  $q_d$  times, where it must be that  $C \neq C_b$  in the guess stage. We denote the advantages by  $\text{Adv}_{\mathcal{PE}, I}^{\text{s-cca}}(B)$  and  $\text{Adv}_{\mathcal{PE}, I}^{\text{s-cca}}(t, q_d)$ , respectively.

### 3 Multi-Recipient Encryption Scheme

Suppose that there are  $n$  recipients. Let  $N \stackrel{\text{def}}{=} \{1, \dots, n\}$ . We define (*single*-plaintext, multi-recipient) public-key encryption schemes and (*multi*-plaintext, multi-recipient) public-key encryption schemes as follows.

- In a (*single*-plaintext, multi-recipient) public-key encryption scheme, a sender sends the same plaintext  $M$  secretly to a subset of recipients  $S \subseteq N$  by broadcasting a ciphertext  $C_S$ .
- In a (*multi*-plaintext, multi-recipient) public-key encryption scheme, a sender sends an independent plaintext  $M_i$  secretly to each recipient  $i \in S$  by broadcasting a ciphertext  $C_S$ .

### 3.1 “Shortened Ciphertext” Property

A multi-recipient public-key encryption scheme is naturally constructed from a single-recipient public-key encryption scheme  $\mathcal{PE} = (\mathcal{K}, \mathcal{E}, \mathcal{D})$  as follows. The key generation algorithm runs  $\mathcal{K}(I)$   $n$  times independently. A ciphertext  $C_N$  is

$$C_N = \mathcal{E}_{pk_1}(M_1) || \cdots || \mathcal{E}_{pk_n}(M_n),$$

where  $||$  denotes concatenation. We call this scheme the *trivial multi-recipient* scheme.

Bellare et al. [2] proved that the trivial multi-recipient scheme is secure in the sense of indistinguishability if  $\mathcal{PE}$  is secure in the same sense. Baudron et al. [1] proved the same result independently. However, the length of the ciphertext of the trivial multi-recipient scheme is  $n$  times larger than that of the single-recipient scheme.

In this paper, we consider multi-recipient public-key encryption schemes such that (1) the length of the ciphertext is almost a half (or less) of the trivial multi-recipient scheme and (2) the security is still almost the same as the underlying single-recipient scheme. We say that such a scheme has a “*shortened ciphertext*” property.

### 3.2 Our Model

For a single-recipient public-key encryption scheme  $\mathcal{PE} = (\mathcal{K}, \mathcal{E}, \mathcal{D})$ , we define a (multi-plaintext, multi-recipient) public-key encryption scheme  $\mathcal{PE}^n = (\mathcal{K}^n, \mathcal{E}^n, TAKE)$  as follows.

- The key generation algorithm  $\mathcal{K}^n$  outputs  $\underline{pk} \stackrel{\text{def}}{=} (pk_1, \dots, pk_n)$  and  $\underline{sk} \stackrel{\text{def}}{=} (sk_1, \dots, sk_n)$  on input some global information  $I$ , where  $(pk_i, sk_i)$  is a pair of encryption/decryption keys of recipient  $i$ .
- For  $S = \{1_1, \dots, i_s\}$ , let  $M_{i_j}$  be a plaintext for recipient  $i_j \in S$ . Let  $\underline{M}_S \stackrel{\text{def}}{=} (M_{i_1}, \dots, M_{i_s})$ . Then the encryption algorithm  $\mathcal{E}^n$  computes a ciphertext  $C_S$  for  $\underline{M}_S$  on input  $\underline{pk}$ ,  $S$  and  $\underline{M}_S$ ; we write  $C_S \stackrel{R}{\leftarrow} \mathcal{E}_{\underline{pk}}^n(S, \underline{M}_S)$ .
- $TAKE$  is a hash function that takes a part of a ciphertext as follows. For  $T \subset S \subseteq N$ , it outputs  $C_T$  on input  $T, S$  and  $C_S$ . We write  $C_T \leftarrow TAKE_T(C_S)$ .

Especially, for  $i \in S$ , we write  $C_i \leftarrow TAKE_i(C_S)$ .

We require that  $\mathcal{D}_{sk_i}(\text{TAKE}_i(C_S)) = M_i$  for all  $i \in S$  and any  $M_i$ .

A (single-plaintext, multi-recipient) public-key encryption scheme is defined similarly.

**Remark 3.1** *In our multi-recipient schemes, the decryption algorithm is the same as the single-recipient scheme. Therefore, no extra cost is required for each recipient.*

### 3.3 Security

We generalize the definition of security for the multi-recipient setting given by Bellare et al. [2] to (multi-plaintext, multi-recipient) schemes as follows.

We consider an experiment as follows. At the beginning, a challenge bit  $b$  is randomly chosen and fixed. An adversary  $B$  is provided with the encryption oracle  $\mathcal{E}_{pk}^n$  and it is allowed to query  $(S, \underline{M}_S^0, \underline{M}_S^1)$  at most  $q_e$  times.  $\mathcal{E}_{pk}^n$  returns a ciphertext  $\mathcal{E}_{pk}^n(S, \underline{M}_S^b)$ . (Since  $b$  is fixed at the beginning, the same  $b$  is used across all the queries.)  $B$  finally outputs a bit  $\tilde{b}$ . We require that  $|M_{i_j}^0| = |M_{i_j}^1|$  for all  $i_j \in S$ , where  $\underline{M}_S^0 = (M_{i_1}^0, \dots, M_{i_s}^0)$  and  $\underline{M}_S^1 = (M_{i_1}^1, \dots, M_{i_s}^1)$ .

Each time,  $B$  can choose  $(S, \underline{M}_S^0, \underline{M}_S^1)$  arbitrarily, where  $S$  as well as  $(\underline{M}_S^0, \underline{M}_S^1)$  may be related to his other queries to  $\mathcal{E}_{pk}^n$ . Then the security of  $\mathcal{PE}^n$  against chosen-plaintext attack is defined as follows.

**Definition 3.1** *For  $b = 0$  and  $1$ , define the experiment as follows.*

$$(\underline{pk}, \underline{sk}) \xleftarrow{R} K^n(I), \tilde{b} \leftarrow B^{\mathcal{E}_{pk}^n}(I, \underline{pk}).$$

Let

$$\begin{aligned} \text{Adv}_{\mathcal{PE}^n, I}^{n\text{-cpa}}(B) &\stackrel{\text{def}}{=} \Pr(\tilde{b} = 0 \mid b = 0) - \Pr(\tilde{b} = 0 \mid b = 1) \\ \text{Adv}_{\mathcal{PE}^n, I}^{n\text{-cpa}}(t, q_e) &\stackrel{\text{def}}{=} \max_B \text{Adv}_{\mathcal{PE}^n, I}^{n\text{-cpa}}(B), \end{aligned}$$

where the maximum is over all  $B$  with time-complexity  $t$ .

In the superscript,  $n$ - denotes "n recipients".

**Definition 3.2** We say that  $\mathcal{PE}^n$  is secure against chosen-plaintext attack if  $\text{Adv}_{\mathcal{PE}^n, I}^{n\text{-cpa}}(t)$  is negligible for polynomially bounded  $t$ , where the complexity is measured as a function of a security parameter.

The security against chosen-ciphertext attack is defined similarly except for that the adversary  $B$  gets  $n$  decryption oracles  $\mathcal{D}_{sk_1}, \dots, \mathcal{D}_{sk_n}$ . It is allowed to query any ciphertext  $C$  to any decryption oracle  $\mathcal{D}_{sk_i}$  at most  $q_d$  times for each  $i$ , where it must be that  $C \neq \text{TAKE}_i(C_S)$  for any output  $C_S$  of the encryption oracle  $\mathcal{E}_{pk}$ . We denote the advantages by  $\text{Adv}_{\mathcal{PE}^n, I}^{n\text{-cca}}(B)$  and  $\text{Adv}_{\mathcal{PE}^n, I}^{n\text{-cca}}(t, q_e, q_d)$ , respectively.

The security of (single-plaintext, multi-recipient) schemes is defined similarly. For simplicity, the same notation as above will be used.

**Remark 3.2** In the definition of Bellare et al. [2], (i)  $|S| = 1$  and there are  $n$  encryption oracles  $\mathcal{E}_{pk_1}, \dots, \mathcal{E}_{pk_n}$ . (ii)  $B$  is allowed to query at most  $q_e$  times to each  $\mathcal{E}_{pk_i}$ . It is easy to see that our definition is more general if we ignore (ii).

### 3.4 Sufficient Condition

We say that an adversary is type 0 if  $q_e = 1$  and his query to  $\mathcal{E}_{pk}^n$  is  $(N, \underline{M}_N^0, \underline{M}_N^1)$ . That is, we consider an adversary which runs in two stages, the find stage and the guess stage, as in the single-recipient case.

**Definition 3.3** Let  $\text{AdvTO}_{\mathcal{PE}^n, I}^{n\text{-cpa}}(t)$  be the  $\max_B \text{Adv}_{\mathcal{PE}^n, I}^{n\text{-cpa}}(B)$ , where the maximum is over all type 0 adversaries  $B$  with time-complexity  $t$ . Define  $\text{AdvTO}_{\mathcal{PE}^n, I}^{n\text{-cca}}(t, q_d)$  similarly.

The next lemma shows that  $\mathcal{PE}^n$  is secure if  $\text{AdvTO}_{\mathcal{PE}^n, I}^{n\text{-x}}(t)$  is negligible, where  $x = \text{cpa}$  or  $\text{cca}$ . Therefore, we do not have to evaluate  $\text{Adv}_{\mathcal{PE}^n, I}^{n\text{-x}}(t, q_e)$  directly.

Let  $T_n$  denote the time to compute a ciphertext  $C_N = \mathcal{E}_{pk}^n(N, \underline{M}_N)$ .

**Lemma 3.1** In an  $n$ -recipient broadcast/multicast public-key encryption scheme  $\mathcal{PE}^n$ ,

$$\begin{aligned} \text{Adv}_{\mathcal{PE}^n, I}^{n\text{-cpa}}(t, q_e) &\leq q_e \cdot \text{AdvTO}_{\mathcal{PE}^n, I}^{n\text{-cpa}}(t'), \\ \text{Adv}_{\mathcal{PE}^n, I}^{n\text{-cca}}(t, q_e, q_d) &\leq q_e \cdot \text{AdvTO}_{\mathcal{PE}^n, I}^{n\text{-cca}}(t', q_d), \end{aligned}$$

where  $t' = t + O(q_e T_n)$ .

A proof is given in Appendix.

## 4 Multi-Recipient "ElGamal" Encryption Scheme

In this section, we show a (multi-plaintext, multi-recipient) ElGamal scheme which has the "*shortened ciphertext*" property. Let  $\mathcal{G}$  be a group with a prime order  $p$  and let  $g$  be a generator of  $\mathcal{G}$ . Let  $I = (p, g)$  be the global information.

Let  $T^{\text{exp}}$  denote the time needed to perform an exponentiation in  $\mathcal{G}$ .

### 4.1 ElGamal scheme and DDH problem

Informally, the decision Diffie-Hellman (DDH) problem is stated as follows. Given  $g^x, g^y, g^z$ , decide if  $z = xy \bmod p$  with nonnegligible probability. Formally, let

$$\begin{aligned} DH &\stackrel{\text{def}}{=} \{(g^x, g^y, g^{xy}) \mid x \in \mathbb{Z}_p, y \in \mathbb{Z}_p\} \\ RA &\stackrel{\text{def}}{=} \{(g^x, g^y, g^z) \mid x \in \mathbb{Z}_p, y \in \mathbb{Z}_p, z \in \mathbb{Z}_p\}. \end{aligned}$$

Let  $D$  be a distinguisher which outputs 0 or 1. Define

$$\begin{aligned} \text{Adv}_{p,g}^{ddh}(D) &\stackrel{\text{def}}{=} \Pr[D(X) = 0 \mid X \in DH] - \Pr[D(X) = 0 \mid X \in RA], \\ \text{Adv}_{p,g}^{ddh}(t) &\stackrel{\text{def}}{=} \max_D \text{Adv}_{p,g}(D), \end{aligned}$$

where the maximum is over all  $D$  with "time-complexity"  $t$ . The DDH assumption is that  $\text{Adv}_{p,g}^{ddh}(t)$  is negligible.

ElGamal encryption scheme  $\mathcal{EG} = (\mathcal{K}, \mathcal{E}, \mathcal{D})$  is as follows.

$$\begin{aligned} \mathcal{K}(I) &: sk = x, pk = X(\leftarrow g^x), \text{ where } x \xleftarrow{R} \mathbb{Z}_p. \\ \mathcal{E}_{I,X}(M) &: (Y, W) = (g^r, M \cdot X^r), \text{ where } r \xleftarrow{R} \mathbb{Z}_p. \\ \mathcal{D}_{I,x}(Y, W) &: M \leftarrow W \cdot Y^{-x}. \end{aligned}$$

It is well known that ElGamal scheme is secure in the sense of indistinguishability against chosen plaintext attack under the DDH assumption.

### 4.2 Proposed Scheme

Now we present the proposed (multi-plaintext, multi-recipient) ElGamal scheme  $\mathcal{EG}^n = (\mathcal{K}^n, \mathcal{E}^n, \text{TAKE})$ . The key generation algorithm  $\mathcal{K}^n(I)$  runs  $\mathcal{K}(I)$   $n$  times independently. Let  $x_i$  be the secret key and  $X_i (= g^{x_i})$  be the public-key of recipient  $i$ .

For  $S = \{1_1, \dots, i_s\}$ , let  $M_{i_j}$  be a plaintext for recipient  $i_j \in S$ . Then a ciphertext for  $S$  is

$$C_S = (g^r, M_{i_1} X_{i_1}^r, \dots, M_{i_s} X_{i_s}^r),$$

where  $r \xleftarrow{R} \mathbb{Z}_p$ .  $TAKE_i$  is defined as  $(g^r, M_i X_i^r) \leftarrow TAKE_i(C_S)$ . For  $T \subset S \subseteq N$ ,  $C_T \leftarrow TAKE_T(C_S)$  is defined naturally.

We will show that our scheme has the “*shortened ciphertext*” property. First, in the trivial multi-recipient scheme, a ciphertext is

$$C_S^{trivial} = (g^{r_{i_1}}, M_{i_1} X_{i_1}^{r_{i_1}}) || \dots || (g^{r_{i_s}}, M_{i_s} X_{i_s}^{r_{i_s}}).$$

Therefore, in our scheme, the size of the ciphertext is almost a half of that of the trivial multi-recipient scheme. We next prove that our scheme is still secure. More precisely, we prove that our scheme is secure in the sense of indistinguishability against chosen plaintext attack under the DDH assumption.

**Lemma 4.1** *In the proposed (multi-plaintext, multi-recipient) ElGamal encryption scheme,*

$$\text{AdvTO}_{\mathcal{EG}^n(p,g)}^{n\text{-cpa}}(t) \leq 2 \cdot \text{Adv}_{p,g}^{\text{ddh}}(t') + \frac{1}{p}, \quad (4)$$

where  $t' = t + O(n \cdot T^{\text{exp}})$ .

A proof is given in Appendix. From lemma 4.1 and lemma 3.1, we obtain the following theorem.

**Theorem 4.1** *In the proposed (multi-plaintext, multi-recipient) ElGamal encryption scheme,*

$$\text{Adv}_{\mathcal{EG}^n(p,g)}^{n\text{-cpa}}(t, q_e) \leq q_e (2 \cdot \text{Adv}_{p,g}^{\text{ddh}}(t') + \frac{1}{p}), \quad (5)$$

where  $t' = t + O(q_e n \cdot T^{\text{exp}})$ .

The concrete security of the trivial multi-recipient ElGamal encryption scheme derived by Bellare et al. [2] satisfies the same equation as eq.(4). Hence, the coefficient  $q_e$  in eq.(5) can be considered as the cost for the “*shortened ciphertext*” property.

### 4.3 S/MIME CMS

S/MIME CMS (IETF RFC 2630) is a (single-plaintext, multi-recipient) scheme such that

$$C_S = (g^r, \text{Wrap}(X_{i_1}^r, K), \dots, \text{Wrap}(X_{i_s}^r, K)),$$

where  $K$  is a content-encryption key to be transported,  $\text{Wrap}$  is a symmetric key-wrapping operation.

The  $\text{Wrap}$  operation takes the role of the multiplication in the basic ElGamal scheme. Therefore, Theorem 4.1 shows that this scheme is secure if  $\text{Wrap}$  is secure enough.

## 5 Multi-Recipient "Cramer-Shoup" Encryption Scheme

In this section, we first show the concrete security of the hash-free variant of Cramer-Shoup scheme. We next present a (multi-plaintext, multi-recipient) hash-free Cramer-Shoup scheme which has the "*shortened ciphertext*" property.

Let  $\mathcal{G}$  be a group with a prime order  $p$  and let  $g_1$  be a generator of  $\mathcal{G}$ . Let  $I = (p, g_1)$  be the global information.

### 5.1 Concrete security of the hash-free Cramer-Shoup Scheme

Bellare et al. derived the concrete security of the basic Cramer-Shoup scheme [9, Sec.3] by assuming the security of universal one-way hash functions (UOH) [2]. In this subsection, we derive the concrete security of the hash-free variant of Cramer-Shoup scheme, which does not need to assume UOH.

The hash-free variant of Cramer-Shoup scheme  $\mathcal{CS} = (\mathcal{K}, \mathcal{E}, \mathcal{D})$  is as follows [9, Sec.5.3]. Let  $F$  be a polynomial time computable injection from  $G^3$  to  $(Z_p^*)^k$  for some  $k$ . Let  $(pk, sk)$  be

$$\begin{aligned} sk &: z, x_1, x_2, (y_{11}, y_{12}), \dots, (y_{k1}, y_{k2}), \\ &\text{where each element is randomly taken from } Z_p. \\ pk &: g_2, h(= g_1^z), c(= g_1^{x_1} g_2^{x_2}), d_1(= g_1^{y_{11}} g_2^{y_{12}}), \dots, d_k(= g_1^{y_{k1}} g_2^{y_{k2}}), \\ &\text{where } g_2 \text{ is randomly chosen from } G. \end{aligned}$$

For a plaintext  $M$ , let a ciphertext  $(u_1, u_2, e, v)$  be

$$u_1 = g_1^r, u_2 = g_2^r, e = h^r M, v = (cd_1^{\alpha_1} \dots d_k^{\alpha_k})^r,$$

where  $r \xleftarrow{R} \mathbb{Z}_p$  and  $(\alpha_1, \dots, \alpha_k) = F(u_1, u_2, e)$ .

On input  $(u_1, u_2, c, v)$ , the decryption algorithm  $\mathcal{D}_{sk}$  first computes  $F(u_1, u_2, e) = (\alpha_1, \dots, \alpha_k)$ . Next if

$$v = u_1^{x_1 + \alpha_1 y_{11} + \dots + \alpha_k y_{k1}} u_2^{x_2 + \alpha_1 y_{12} + \dots + \alpha_k y_{k2}}, \quad (6)$$

Then  $\mathcal{D}_{sk}$  outputs

$$M \leftarrow e / u_1^z. \quad (7)$$

Otherwise,  $\mathcal{D}_{sk}$  outputs *reject*. Let

$$\epsilon \stackrel{\text{def}}{=} \left(1 - \frac{1}{p}\right) \frac{q_d}{p} + \frac{1}{p}.$$

**Theorem 5.1** *In the hash-free Cramer-Shoup scheme,*

$$\text{Adv}_{\mathcal{CS}(p, g_1)}^{\text{s-cca}}(t, q_d) \leq 2 \cdot \text{Adv}_{p, g_1}^{\text{ddh}}(t') + 3\epsilon, \quad (8)$$

where  $t' = t + O(q_d \cdot T^{\text{exp}})$ .

A proof will be given in the final paper.

## 5.2 Proposed Scheme

Now the proposed (multi-plaintext, multi-recipient) hash-free Cramer-Shoup scheme  $\mathcal{CS}^n = (\mathcal{K}^n, \mathcal{E}^n, \text{TAKE})$  is described as follows. The key generation algorithm  $\mathcal{K}^n(I)$  runs  $\mathcal{K}(I)$   $n$  times independently with a restriction such that  $g_2$  is common for all  $pk_i$ , where  $pk_i = (g_2, h_i, c_i, d_{1i}, \dots, d_{ki})$ . That is, the encryption keys  $pk_i$  are not independent of each other while the secret keys  $sk_i$  are independently chosen. This is possible because  $w$  is not a part of  $sk_i$ , where  $g_2 = g_1^w$ .

For  $S = \{1, \dots, i_s\}$ , let  $M_i$  be a plaintext for recipient  $i \in S$ . Then a ciphertext for  $S$  is

$$C_S = (u_1, u_2, e_{i_1}, v_{i_1}, \dots, e_{i_n}, v_{i_n})$$

such that  $u_1 = g_1^r$ ,  $u_2 = g_2^r$  and  $e_i = h_i^r M_i$ ,  $v_i = (c_i d_{1i}^{\alpha_{1i}} \dots d_{ki}^{\alpha_{ki}})^r$ , where  $r \xleftarrow{R} \mathbb{Z}_p$  and  $(\alpha_{1i}, \dots, \alpha_{ki}) = F(u_1, u_2, e_i)$ .  $\text{TAKE}_i$  is defined as  $(u_1, u_2, e_i, v_i) \leftarrow \text{TAKE}_i(C_S)$ .  $C_S \leftarrow \text{TAKE}_S(C_N)$  is defined naturally.

Note that the size of the ciphertext of our scheme is almost a half of the trivial multi-recipient scheme. We next prove that our scheme is still secure. More precisely, we prove that our scheme is secure in the sense of indistinguishability against chosen ciphertext attack under the DDH assumption.

**Lemma 5.1** *In the proposed (multi-plaintext,multi-recipient) Cramer-Shoup scheme,*

$$\text{AdvTO}_{\mathcal{CS}^n, (p, g_1)}^{n\text{-cca}}(t, q_d) \leq 2 \cdot \text{Adv}_{p, g_1}^{\text{ddh}}(t') + 3n\epsilon, \quad (9)$$

where  $t' = t + O(n \cdot q_d \cdot T^{\text{exp}})$ .

The proof is similar to that of Theorem 5.1. From lemma 5.1 and lemma 3.1, we obtain the following theorem.

**Theorem 5.2** *In the proposed (multi-plaintext,multi-recipient) Cramer-Shoup scheme,*

$$\text{Adv}_{\mathcal{CS}^n, (p, g_1)}^{n\text{-cca}}(t, q_d) \leq q_e(2 \cdot \text{Adv}_{p, g_1}^{\text{ddh}}(t') + 3n\epsilon), \quad (10)$$

where  $t' = t + O(n \cdot q_d \cdot T^{\text{exp}}) + O(q_e n T^{\text{exp}})$ .

Comparing with the concrete security of the trivial multi-recipient (basic) Cramer-Shoup scheme given by Bellare et al. [2], we can see that our scheme takes no extra cost for the “shortened ciphertext” property except negligible factors.

## 6 Multi-Recipient Hybrid Encryption Scheme

### 6.1 Overview

Bellare and Rogaway showed that eq.(1) is secure in the sense of indistinguishability against chosen plaintext attack if  $\mathcal{E}_{pk}$  is a trapdoor oneway permutation. However, this does not imply that eq.(2) is secure. Indeed, it is not secure if  $\mathcal{E}_{pk}$  is RSA as mentioned in Sec.1.1.1. On the other hand, the results of [2, 1] imply only that the latter part  $\mathcal{E}_{pk_1}(r) || \cdots || \mathcal{E}_{pk_n}(r)$  of eq.(2) is secure in the sense of indistinguishability if  $\mathcal{E}_{pk}(r)$  is secure in the same sense.

In this section, we formally prove that eq.(2) is secure in the sense of indistinguishability against chosen plaintext attack if  $\mathcal{E}_{pk}$  is secure in the same sense.

More generally, we prove that there exists a (single-plaintext,multi-recipient) *hybrid* encryption scheme  $\mathcal{H}^n = (\mathcal{K}_H^n, \mathcal{E}_H^n, TAKEH)$  which is secure in the sense of indistinguishability against chosen plaintext (ciphertext, respectively) attack if there exists a (multi-plaintext,multi-recipient) public-key encryption scheme  $\mathcal{PE}^n = (\mathcal{K}^n, \mathcal{E}^n, TAKE)$  which is secure in the same sense against type 0 adversaries.

For example, we can use Rabin-SAEP, RSA-SAEP<sup>+</sup> [4] or Cramer-Shoup scheme [9] as the underlying single-recipient scheme secure against chosen *ciphertext* attack.

In what follows, let  $\mathcal{PE} = (\mathcal{K}, \mathcal{E}, \mathcal{D})$  be the underlying single recipient public-key scheme. That is,

$$\mathcal{PE} \rightarrow \mathcal{PE}^n \rightarrow \mathcal{H}^n.$$

Remember that  $\mathcal{E}_{pk}^n(S, \underline{r})$  denotes a ciphertext of  $\underline{r} = (r, \dots, r)$  for a subset of recipients  $S = \{i_1, \dots, i_s\}$  in  $\mathcal{PE}^n$ .

## 6.2 IND-CPA Hybrid Scheme

Define a (single-plaintext, multi-recipient) *hybrid* encryption scheme  $\mathcal{H}^n = (\mathcal{K}_H^n, \mathcal{E}_H^n, TAKEH)$  from  $\mathcal{PE}^n = (\mathcal{K}^n, \mathcal{E}^n, TAKE)$  as follows.

Let a ciphertext of  $M$  for a subset of recipients  $S = \{i_1, \dots, i_s\}$  be

$$C_S = \mathcal{E}_{pk}^n(S, \underline{r}) || M \oplus G(r), \quad (11)$$

where  $r$  is a random element and  $G$  is a pseudorandom generator. For  $T \subset S \subseteq N$ , let

$$TAKEH_T(C_S) = TAKE_T(\mathcal{E}_{pk}^n(S, \underline{r})) || M \oplus G(r).$$

Now we prove that  $\mathcal{H}^n$  is secure in the sense of indistinguishability against chosen plaintext attack if  $\mathcal{PE}^n$  is secure in the same sense only against type 0 adversaries under the random oracle model, where  $G$  is modeled as a random oracle.

Suppose that an adversary makes at most  $q_G$  queries to the random oracle  $G$ . Let  $r$  be  $l$ -bits long. We first show that  $\mathcal{H}^n$  is secure against type 0 adversaries if  $\mathcal{PE}^n$  is so.

### Lemma 6.1

$$\text{AdvTO}_{\mathcal{H}^n, I}^{n\text{-cpa}}(t') \leq \text{AdvTO}_{\mathcal{PE}^n, I}^{n\text{-cpa}}(t'') + \frac{q_G}{2^{l-3}}, \quad (12)$$

where  $t'' = t' + O(q_G) + O(n)$ .

A proof is given in Appendix. From lemma 3.1, we have

$$\text{Adv}_{\mathcal{H}^n, I}^{n\text{-cpa}}(t, q_e) \leq q_e \text{AdvTO}_{\mathcal{H}^n, I}^{n\text{-cpa}}(t')$$

where  $t' = t + O(q_e T_n)$ . Therefore, we obtain the following Theorem.

**Theorem 6.1**

$$\text{Adv}_{\mathcal{H}^n, I}^{n\text{-cpa}}(t, q_e) \leq q_e \left( \text{AdvTO}_{\mathcal{PE}^n, I}^{n\text{-cpa}}(t'') + \frac{q_G}{2^{l-3}} \right),$$

where  $t'' = t + O(q_e T_n) + O(q_G) + O(n)$ .

(Proof)

$$T'' = t' + O(q_G) + O(n) = t + O(q_e T_n) + O(q_G) + O(n).$$

Q.E.D.

Suppose that  $\mathcal{PE}^n$  used in eq.(11) is the trivial multi-recipient scheme. For the trivial scheme, the result of Bellare et al. implies that [2]

$$\text{AdvTO}_{\mathcal{PE}^n, I}^{n\text{-cpa}}(t'') \leq n \cdot \text{Adv}_{\mathcal{PE}, I}^{\text{cpa}}(t''')$$

where  $t''' = t'' + O(nT_s)$  and  $T_s$  denotes the time to compute a ciphertext of  $\mathcal{PE}$ . Since  $T_n = nT_s$ , we obtain the following corollary.

**Corollary 6.1** *In the above (single-plaintext, multi-recipient) scheme  $\mathcal{H}^n$ ,*

$$\text{Adv}_{\mathcal{H}^n, I}^{n\text{-cpa}}(t, q_e) \leq q_e \left( n \cdot \text{Adv}_{\mathcal{PE}, I}^{\text{cpa}}(t') + \frac{q_G}{2^{l-3}} \right), \quad (13)$$

where  $t' = t + O(q_G) + O(q_e n T_s)$  and  $T_s$  denotes the time to compute a ciphertext of  $\mathcal{PE}$ .

### 6.3 IND-CCA Hybrid Scheme

First, define a single-recipient hybrid encryption scheme  $\mathcal{HY} = (\mathcal{K}_Y, \mathcal{E}_Y, \mathcal{D}_Y)$  from  $\mathcal{PE}$  as follows. Let a ciphertext of  $M$  be  $C = c_1 || c_2 || c_3$  with

$$c_1 = M \oplus G(r), \quad c_2 = H(r || M), \quad c_3 = \mathcal{E}_{pk}(r),$$

where  $r$  is a random element,  $H$  is a hash function and  $G$  is a pseudorandom generator. The decryption algorithm  $\mathcal{D}_Y$  is defined as

$$\mathcal{D}_{Ysk}(c_1 || c_2 || c_3) = \begin{cases} \text{reject} & \text{if } \mathcal{D}_{sk}(c_3) = \text{reject} \text{ or } c_2 \neq H(\hat{r} || c_1 \oplus G(\hat{r})) \\ c_1 \oplus G(\hat{r}) & \text{otherwise,} \end{cases}$$

where  $\hat{r} = \mathcal{D}_{sk}(c_3)$ .

Next define a (single-plaintext, multi-recipient) *hybrid* encryption scheme  $\mathcal{HY}^n = (\mathcal{K}_H^n, \mathcal{E}_H^n, \text{TAKEH})$  from  $\mathcal{PE}^n = (\mathcal{K}^n, \mathcal{E}^n, \text{TAK})$  as follows. Let a

ciphertext of  $M$  for a subset of recipients  $S = \{i_1, \dots, i_s\}$  be  $C_S = c_1 || c_2 || c_3$ , where

$$c_1 = M \oplus G(r), \quad c_2 = H(r || M), \quad c_3 = \mathcal{E}_{pk}^n(S, \underline{r}). \quad (14)$$

For  $T \subset S \subseteq N$ , let

$$TAKEH_T(C_S) = c_1 || c_2 || TAKE_T(\mathcal{E}_{pk}^n(S, \underline{r})).$$

Now we prove that  $\mathcal{HY}^n$  is secure in the sense of indistinguishability against chosen ciphertext attack if  $\mathcal{PE}^n$  is secure in the same sense only against type 0 adversaries under the random oracle model, where  $G$  and  $H$  are modeled as random oracles.

Suppose that an adversary makes at most  $q_G$  queries to the  $G$ -oracle, at most  $q_H$  queries to the  $H$ -oracle and at most  $q_d$  queries to each decryption oracle  $\mathcal{D}_{sk_i}$ . Let  $r$  be  $l$ -bits long,  $M$  be  $k$ -bits long,  $r || M$  be  $m$ -bits long and  $H(r || M)$  be  $h$  bits long. Define

$$\sigma \stackrel{\text{def}}{=} \frac{q_G + q_H}{2^{l-2}} + \frac{nq_d}{2^h}.$$

We first show that  $\mathcal{HY}^n$  is secure against type 0 adversaries if  $\mathcal{PE}^n$  is so.

**Lemma 6.2**

$$\text{AdvTO}_{\mathcal{HY}^n, I}^{n\text{-cca}}(t', q_d) \leq \text{AdvTO}_{\mathcal{PE}^n, I}^{n\text{-cca}}(t'', q_d) + \sigma,$$

where  $t'' = t' + O(q_G) + O(q_H) + O(q_d) + O(n)$ .

A proof is given in Appendix. From lemma 3.1, we have

$$\text{Adv}_{\mathcal{HY}^n, I}^{n\text{-cpa}}(t, q_e, q_d) \leq q_e \text{AdvTO}_{\mathcal{HY}^n, I}^{n\text{-cpa}}(t', q_d)$$

where  $t' = t + O(q_e T_n)$ . Therefore, we obtain the following Theorem.

**Theorem 6.2**

$$\text{Adv}_{\mathcal{HY}^n, I}^{n\text{-cca}}(t, q_e, q_d) \leq q_e \left( \text{AdvTO}_{\mathcal{PE}^n, I}^{n\text{-cca}}(t'', q_d) + \sigma \right),$$

where  $t'' = t + O(q_e T_n) + O(q_G) + O(q_H) + O(q_d) + O(n)$ .

Suppose that  $\mathcal{PE}^n$  used in eq.(14) is the trivial multi-recipient scheme. For the trivial scheme, the result of Bellare et al. implies that [2]

$$\text{AdvTO}_{\mathcal{PE}^n, I}^{n\text{-cca}}(t'', q_d) \leq n \cdot \text{Adv}_{\mathcal{PE}, I}^{\text{cca}}(t''', q_d),$$

where  $t''' = t'' + O(nT_s)$  and  $T_s$  denotes the time to compute a ciphertext of  $\mathcal{PE}$ . Since  $T_n = nT_s$ , we obtain the following corollary.

**Corollary 6.2** *In the above (single-plaintext,multi-recipient) scheme  $\mathcal{HY}^n$ ,*

$$\text{Adv}_{\mathcal{H}^n, I}^{n\text{-cca}}(t, q_e, q_d) \leq q_e(n \cdot \text{Adv}_{\mathcal{PE}, I}^{\text{cca}}(t', q_d) + \sigma), \quad (15)$$

*where  $t' = t + O(q_e n T_s) + (q_G) + O(q_H) + O(q_d)$  and  $T_s$  denotes the time to compute a ciphertext of  $\mathcal{PE}$ .*

#### 6.4 Improvement on Multi-Recipient ElGamal and Cramer-Shoup

In our (multi-plaintext,multi-recipient) ElGamal encryption scheme, suppose that  $M = M_{i_1} = \dots = M_{i_s}$ . In this case, let a ciphertext be

$$\bar{C} = (Mg^r, X_{i_1}^r, \dots, X_{i_s}^r).$$

This scheme is better than our scheme of Sec.4.2 because  $M$  is multiplied once. The security is proved similarly. Further, we can consider a hybrid scheme such that

$$\bar{C}' = (Kg^r, X_{i_1}^r, \dots, X_{i_s}^r) || G(K) \oplus M.$$

We can improve our multi-recipient Cramer-Shoup scheme similarly.

## A Proof of Lemma 3.1

We show a proof for (multi-plaintext, multi-recipient) schemes against chosen-plaintext attack. The proofs for the other cases are similar. Let  $B$  be an adversary which has time-complexity  $t$  and makes at most  $q_e$  queries. We will design an type 0 adversary  $D_B$  with time-complexity at most  $t'$ .

Similar to [2], we consider a hybrid experiment with a parameter  $l$  such that  $0 \leq l \leq q_e$  as follows.

**Experiment- $l$ :** Let the  $i$ -th query of  $B$  be  $(S, \underline{M}_S^0, \underline{M}_S^1)$ . If  $i \leq l$ , then  $\mathcal{E}_{pk}$  returns  $\mathcal{E}_{pk}(S, \underline{M}_S^1)$ . Otherwise, it returns  $\mathcal{E}_{pk}(S, \underline{M}_S^0)$ .

Let

$$p_l \stackrel{\text{def}}{=} \Pr[\tilde{b} = 0 \text{ in Experiment-}l].$$

Then it is easy to see that

$$\mathbf{Adv}_{\mathcal{P}^{\mathcal{E}^n, I}}^{n\text{-cpa}}(B) = p_0 - p_{q_e}.$$

Next our  $D_B$  works as follows. On input  $(I, \underline{pk})$ ,  $D_B$  chooses  $l$  randomly such that  $1 \leq l \leq q_e$ . It runs  $B$  by giving  $(I, \underline{pk})$  to  $B$ . Let the  $i$ -th query of  $B$  be  $(S, \underline{M}_S^0, \underline{M}_S^1)$ .

1. If  $i < l$ , then  $D_B$  returns  $C_S^1 \stackrel{R}{\leftarrow} \mathcal{E}_{pk}(S, \underline{M}_S^1)$ .
2. If  $i > l$ , then  $D_B$  returns  $C_S^0 \stackrel{R}{\leftarrow} \mathcal{E}_{pk}(S, \underline{M}_S^0)$ .
3. If  $i = l$ , then  $D_B$  queries  $(N, \underline{M}_N^0, \underline{M}_N^1)$  to his encryption oracles, where  $\underline{M}_S^0$  and  $\underline{M}_S^1$  are naturally embedded in  $\underline{M}_N^0$  and  $\underline{M}_N^1$ , respectively. The oracle returns  $C_N^b \stackrel{R}{\leftarrow} \mathcal{E}_{pk}(N, \underline{M}_N^b)$  to  $D_B$ .  $D_B$  finally gives  $C_S^b = \text{TAKE}_S(C_N^b)$  to  $B$ .

Suppose that  $B$  outputs  $\tilde{b}$  finally. Then  $D_B$  outputs  $\tilde{b}$ .

Now we can see that

$$\begin{aligned}\Pr(\tilde{b} = 0 \mid b = 0) &= (p_0 + \cdots p_{q_e-1})/q_e \\ \Pr(\tilde{b} = 0 \mid b = 1) &= (p_1 + \cdots p_{q_e})/q_e\end{aligned}$$

because  $l$  is randomly chosen. Therefore,

$$\mathbf{Adv}_{\mathcal{P}_{\mathcal{E}^n, I}}^{n\text{-cpa}}(D_B) = (p_0 - p_{q_e})/q_e = \mathbf{Adv}_{\mathcal{P}_{\mathcal{E}^n, I}}^{n\text{-cpa}}(B)/q_e.$$

Hence

$$\mathbf{Adv}_{\mathcal{P}_{\mathcal{E}^n, I}}^{n\text{-cpa}}(B) = q_e \cdot \mathbf{Adv}_{\mathcal{P}_{\mathcal{E}^n, I}}^{n\text{-cpa}}(D_B).$$

By taking the maximum, we obtain that

$$\mathbf{Adv}_{\mathcal{P}_{\mathcal{E}^n, I}}^{n\text{-cpa}}(t, q_e) \leq q_e \cdot \mathbf{AdvTO}_{\mathcal{P}_{\mathcal{E}^n, I}}^{n\text{-cpa}}(t').$$

Finally, the overhead of  $D_B$  is to pick the random number  $l$  and execute some conditional statements. It is  $O(q_e \cdot T_n)$ .

## B Proof of Lemma 4.1

By extending the result of Stadler [15, in the proof of Proposition 1] and Naor and Reingold [14, lemma 3.2], Bellare et al. proved the following proposition [2].

**Proposition B.1** [2] *There is a probabilistic algorithm  $R$  such that on input  $g^a, g^b, g^c$ ,  $R$  outputs  $g^{b'}, g^{c'}$ , where  $b'$  is random and*

$$c' = \begin{cases} ab' \bmod p & \text{if } c = ab \bmod p \\ \text{random} & \text{if } c \neq ab \bmod p \end{cases}$$

$R$  runs in  $O(T^{\text{exp}})$  time.

Now we show a proof of lemma 4.1. Let  $B$  be a type 0 adversary attacking the proposed scheme with time-complexity at most  $t$ . We will design an adversary  $D_B$  for the DDH problem, where  $D_B$  has time complexity at most  $t'$ .

Let the input to  $D_B$  be  $g^r, g^x, g^z$ .  $D_B$  runs  $R$  of Proposition B.1  $n$  times independently on input  $(g^r, g^x, g^z)$ . Then  $R$  outputs  $X_1 = g^{x_1}, \dots, X_n = g^{x_n}$  and  $Z_1 = g^{z_1}, \dots, Z_n = g^{z_n}$ , where  $x_1, \dots, x_n$  are random and

$$z_i = \begin{cases} rx_i \bmod p & \text{if } z = rx \bmod p \\ \text{random} & \text{if } z \neq rx \bmod p \end{cases}$$

$D_B$  gives  $X_1, \dots, X_n$  to  $B$  as  $n$  public keys and runs  $B$ . Suppose that  $B$  queries  $(M_{0,1}, \dots, M_{0,n})$  and  $(M_{1,1}, \dots, M_{1,n})$  in the find stage. Then  $D_B$  chooses a random bit  $b$  and gives  $\tilde{C} = (g^r, M_{b,1} \cdot Z_1, \dots, M_{b,n} \cdot Z_n)$  to  $B$  as a challenge ciphertext. Suppose that  $B$  outputs  $\tilde{b}$  in the guess stage. Finally,  $D_B$  outputs  $b \oplus \tilde{b}$ .

First suppose that  $(g^r, g^x, g^z) \in DH$ . Then  $\tilde{C}$  is a legal ciphertext. Therefore, as shown in eq.(3), we have

$$\Pr(D_B \text{ outputs } 0) = \Pr(\tilde{b} = b) = \frac{1}{2} + \frac{1}{2} \text{Adv}_{\mathcal{EG}^n, (p, g)}^{n\text{-cpa}}(B). \quad (16)$$

Next suppose that  $(g^r, g^x, g^z) \in RA$ . If  $z \neq rx$ , then  $Z_1, \dots, Z_n$  are random and  $\Pr(\tilde{b} = b) = 1/2$ . Hence, we have

$$\begin{aligned} \Pr(D_B \text{ outputs } 0) &= \Pr(\tilde{b} = b) \\ &\leq \frac{1}{2} \left(1 - \frac{1}{p}\right) + \frac{1}{p} = \frac{1}{2} + \frac{1}{2p} \end{aligned} \quad (17)$$

From eq.(16) and eq.(17), we have

$$\begin{aligned} \text{Adv}_{p, g}^{\text{ddh}}(D_B) &\geq \frac{1}{2} \text{Adv}_{\mathcal{EG}^n, (p, g)}^{n\text{-cpa}}(B) - \frac{1}{2p} \\ \text{Adv}_{\mathcal{EG}^n, (p, g)}^{n\text{-cpa}}(B) &\leq 2 \text{Adv}_{p, g}^{\text{ddh}}(D_B) + \frac{1}{p} \end{aligned}$$

By taking the maximum, we have

$$\text{AdvTO}_{\mathcal{EG}^n, (p, g)}^{n\text{-cpa}}(t) \leq 2 \cdot \text{Adv}_{p, g}^{\text{ddh}}(t') + \frac{1}{p}.$$

It is easy to see that  $t' = t + O(n \cdot T^{\text{exp}})$ .

## C Proof of Theorem 5.1

$(u'_1, u'_2, e', v')$  is called valid if  $u'_1 = g_1^{r'}$  and  $u'_2 = g_2^{r'}$  for some  $r'$ . Otherwise, it is called invalid.

We first consider a slightly modified version of  $\mathcal{CS}$  such that  $h = g_1^{z_1} g_2^{z_2}$ , where  $z_1 \xleftarrow{R} Z_p$  and  $z_2 \xleftarrow{R} Z_p$ , and eq.(7) is replaced by

$$M \leftarrow e / u_1^{z_1} u_2^{z_2}. \quad (18)$$

We denote this modified version by  $m\mathcal{CS}$ .

**Lemma C.1** *In the modified version,*

$$\mathbf{Adv}_{m\mathcal{CS},(p,g_1)}^{\text{s-cca}}(t, q_d) \leq 2 \cdot \mathbf{Adv}_{p,g_1}^{\text{ddh}}(t') + \epsilon,$$

where  $t' = t + O(q_d \cdot T^{\text{exp}})$ .

*Proof.* Let  $B$  be an adversary attacking the modified scheme with time-complexity at most  $t$ . We will design an adversary  $D_B$  for the DDH problem, where  $D_B$  has time complexity at most  $t'$ .

Let the input to  $D_B$  be  $g_2, g_1^{r_1}, g_2^{r_2}$ .  $D_B$  runs  $\mathcal{K}(I)$  and obtains  $(pk, sk)$ .  $D_B$  gives  $pk$  to  $B$  and runs  $B$ .  $D_B$  can simulate the decryption oracle  $\mathcal{D}_{sk}$  because he knows  $sk$ .

Suppose that  $B$  queries  $M_0$  and  $M_1$  in the find stage. Then  $D_B$  chooses a random bit  $b$  and computes a challenge ciphertext  $C = (u_1, u_2, e, v)$  such that  $u_1 = g_1^{r_1}, u_2 = g_2^{r_2}$  and

$$\begin{aligned} e &= u_1^{z_1} u_2^{z_2} M_b \\ v &= u_1^{x_1 + \alpha_1 y_{11} + \dots + \alpha_k y_{k1}} u_2^{x_2 + \alpha_1 y_{12} + \dots + \alpha_k y_{k2}} \end{aligned} \quad (19)$$

where  $(\alpha_1, \dots, \alpha_k) = F(u_1, u_2, e)$ .  $D_B$  then gives  $C$  to  $B$ . Suppose that  $B$  outputs  $\tilde{b}$  in the guess stage. Finally,  $D_B$  outputs  $b \oplus \tilde{b}$ .

First suppose that  $(g_2, g_1^{r_1}, g_2^{r_2}) \in DH$ , which means that  $r_1 = r_2$ . In this case, it is easy to see that  $C$  is a legal ciphertext. Therefore, from eq.(3), we have

$$\Pr(D_B \text{ outputs } 0) = \Pr(\tilde{b} = b) = \frac{1}{2} + \frac{1}{2} \mathbf{Adv}_{m\mathcal{CS},(p,g_1)}^{\text{s-cca}}(B) \quad (20)$$

Next suppose that  $(g_2, g_1^{r_1}, g_2^{r_2}) \in RA$ . As shown in [9], it holds that

$$\Pr(\tilde{b} = b \mid \text{the decryption oracle rejects all invalid ciphertexts}) = 1/2 \quad (21)$$

Let

$$p_0 \stackrel{\text{def}}{=} \Pr(\text{at least one invalid ciphertext is accepted}).$$

**Claim C.1**  $p_0 \leq \epsilon$ .

*Proof.* Suppose that  $B$  queries an invalid ciphertext  $C' = (u'_1, u'_2, e', v')$  to the decryption oracle, where

$$u'_1 = g_1^{r'_1}, \quad u'_2 = g_2^{r'_2}$$

with  $r'_1 \neq r'_2$ . Let  $F(u'_1, u'_2, e') = (\alpha'_1, \dots, \alpha'_k)$ . Let  $g_2 = g_1^w$ . First assume that  $w \neq 0$ .

(Find stage) For fixed  $c, d_1, \dots, d_k$ , let  $A_1$  be the set of  $X = (x_1, y_{11}, \dots, y_{k1}, x_2, y_{12}, \dots, y_{k2})$  which can form  $c, d_1, \dots, d_k$ . For a fixed  $v'$ , let  $A_2$  be the set of secret keys which can form  $v'$ . Each  $X$  of  $A_1 \cap A_2$  must satisfy the set of linear equations whose coefficients matrix is

$$\begin{pmatrix} 1 & & & & w & & & \\ & 1 & & & & w & & \\ & & \ddots & & & & \ddots & \\ & & & 1 & & & & w \\ r'_1 & r'_1 \alpha'_1 & \dots & r'_1 \alpha'_k & r'_2 w & r'_2 \alpha'_1 w & \dots & r'_2 \alpha'_k w \end{pmatrix}.$$

where the last row corresponds to the equation about  $v'$ . By the Gauss elimination, we have

$$\begin{pmatrix} 1 & & & & w & & & \\ & 1 & & & & w & & \\ & & \ddots & & & & \ddots & \\ & & & 1 & & & & w \\ 0 & 0 & \dots & 0 & (r'_2 - r'_1)w & (r'_2 - r'_1)\alpha'_1 w & \dots & (r'_2 - r'_1)\alpha'_k w \end{pmatrix}.$$

The last row is linearly independent of the previous rows because  $(r'_2 - r'_1)w \neq 0$  from our assumption. Hence,

$$\Pr(C' \text{ is accepted} \mid w \neq 0) \leq |A_1 \cap A_2|/|A_1| = 1/p.$$

(Guess stage) First suppose that  $(u'_1, u'_2, e') = (u_1, u_2, e)$ . In this case,  $v' \neq v$  because  $(u'_1, u'_2, e', v') \neq (u_1, u_2, e, v)$ . On the other hand,  $v$  satisfies eq.(6) because it is computed by eq.(19). Therefore,  $v'$  does not satisfy eq.(6). Hence,  $(u'_1, u'_2, e', v')$  is rejected.

Next suppose that  $(u'_1, u'_2, e') \neq (u_1, u_2, e)$ . For fixed  $c, d_1, \dots, d_k$  and  $v$ , let  $A'_1$  be the set of  $X = (x_1, y_{11}, \dots, y_{k1}, x_2, y_{12}, \dots, y_{k2})$  which can form  $c, d_1, \dots, d_k, v$ . For a fixed  $v'$ , let  $A'_2$  be the set of secret keys which can form  $v'$ . Each  $X$  of  $A'_1 \cap A'_2$  must satisfy the set of linear equations whose

coefficients matrix is

$$\begin{pmatrix} 1 & & & & w & & & \\ & 1 & & & & w & & \\ & & \ddots & & & & \ddots & \\ & & & 1 & & & & w \\ r_1 & r_1\alpha_1 & \cdots & r_1\alpha_k & r_2w & r_2\alpha_1w & \cdots & r_2\alpha_kw \\ r'_1 & r'_1\alpha'_1 & \cdots & r'_1\alpha'_k & r'_2w & r'_2\alpha'_1w & \cdots & r'_2\alpha'_kw \end{pmatrix}.$$

where the last row corresponds to the equation about  $v'$ . By the Gauss elimination, we have

$$\begin{pmatrix} 1 & & & & w & & & \\ & 1 & & & & w & & \\ & & \ddots & & & & \ddots & \\ & & & 1 & & & & w \\ 0 & 0 & \cdots & 0 & (r_2 - r_1)w & (r_2 - r_1)\alpha_1w & \cdots & (r_2 - r_1)\alpha_kw \\ 0 & 0 & \cdots & 0 & (r'_2 - r'_1)w & (r'_2 - r'_1)\alpha'_1w & \cdots & (r'_2 - r'_1)\alpha'_kw \end{pmatrix}.$$

If  $r_2 - r_1 = 0$ , then the last row is linearly independent of the previous rows because  $(r'_2 - r'_1)w \neq 0$  from our assumption. Suppose that  $r_2 - r_1 \neq 0$ . If the last row depends on the previous rows, then we must have

$$1 = \frac{\alpha_1}{\alpha'_1} = \cdots, \frac{\alpha_k}{\alpha'_k}.$$

Hence  $(\alpha_1, \dots, \alpha_k) = (\alpha'_1, \dots, \alpha'_k)$ . This means that  $(u_1, u_2, e) = (u'_1, u'_2, e')$  because  $F$  is an injection. However, this is a contradiction. Therefore, the last row is linearly independent of the previous rows. Hence,

$$\Pr(C' \text{ is accepted} \mid w \neq 0) \leq |A'_1 \cap A'_2|/|A'_1| = 1/p.$$

In each stage, we see that

$$\Pr(\text{an invalid } C' \text{ is accepted} \mid w \neq 0) \leq 1/p.$$

Now suppose that  $B$  makes at most  $q_d$  queries to the decryption oracle. Then it holds that

$$\Pr(\text{at least one invalid ciphertext is accepted} \mid w \neq 0) \leq q_d/p.$$

Therefore,

$$\Pr(\text{at least one invalid ciphertext is accepted}) \leq \left(1 - \frac{1}{p}\right) \frac{q_d}{p} + \frac{1}{p} = \epsilon.$$

□

Now from eq.(21), we have

$$\begin{aligned} \Pr(D_B \text{ outputs } 0) &= \Pr(\tilde{b} = b) \\ &\leq \frac{1}{2}(1 - p_0) + p_0 = \frac{1}{2} + \frac{1}{2}p_0 \end{aligned} \quad (22)$$

From eq.(20) and eq.(22), we obtain that

$$\begin{aligned} \text{Adv}_{p,g}^{\text{ddh}}(D_B) &\geq \frac{1}{2} \text{Adv}_{m\mathcal{CS},(p,g)}^{\text{s-cca}}(B) - \frac{1}{2}p_0 \\ \text{Adv}_{m\mathcal{CS},(p,g)}^{\text{s-cca}}(B) &\leq 2\text{Adv}_{p,g}^{\text{ddh}}(D_B) + p_0 \end{aligned}$$

By taking the maximum, we have

$$\begin{aligned} \text{Adv}_{m\mathcal{CS},(p,g_1)}^{\text{s-cca}}(t, q_d) &\leq 2 \cdot \text{Adv}_{p,g}^{\text{ddh}}(t') + p_0 \\ &\leq 2 \cdot \text{Adv}_{p,g}^{\text{ddh}}(t') + \epsilon. \end{aligned}$$

It is easy to see that  $t' = t + O(q_d \cdot T^{\text{exp}})$ .

□

Now we show a proof of Theorem 5.1. Let  $B_1$  be an adversary which attacks  $\mathcal{CS}$ . We will design an adversary  $B_2$  which attacks the modified version  $m\mathcal{CS}$  by using  $B_1$  as a subroutine. Let the input to  $B_2$  be  $(I, pk)$ . Then  $B_2$  gives  $(I, pk)$  to  $B_1$  and runs  $B_1$ .

Suppose that  $B_1$  outputs  $(M_0, M_1, \text{state})$  at the end of the find stage. Then  $B_2$  outputs  $(M_0, M_1, \text{state})$  at the end of his find stage. In the guess stage,  $B_2$  gets a challenge ciphertext  $C_b$  for  $M_b$ , where  $b = 0$  or  $1$ .  $B_2$  gives  $(C_b, \text{state})$  to the guess stage of  $B_1$ .  $B_1$  finally outputs  $\tilde{b}$ . Then  $B_2$  outputs  $\tilde{b}$ .

Let  $D_1$  be the decryption oracle for  $B_1$  and  $D_2$  be the decryption oracle for  $B_2$ . If  $B_1$  queries a ciphertext  $C$  to  $D_1$ , then  $B_2$  queries  $C$  to  $D_2$ . If  $D_2$  returns  $\sigma$  to  $B_2$ , then  $B_2$  returns  $\sigma$  to  $B_1$ . We show that  $B_2$  simulates  $D_1$  with overwhelming probability.

Now it holds that  $D_1$  rejects  $C$  if and only if  $D_2$  rejects  $C$  because eq.(6) does not contain  $z, z_1, z_2$ . Next suppose that  $C$  is accepted by  $D_1$  and  $D_2$ . Then there are two cases,  $C$  is valid or  $C$  is invalid. If  $C$  is valid, then  $D_1$  and

$D_2$  return the same  $M$ . This is verified as follows. Let  $C = (u'_1, u'_2, e', v')$ , where  $u'_1 = g_1^{r'}$  and  $u'_2 = g_2^{r'}$  for some  $r'$ . Then in  $\mathcal{CS}$ ,

$$h^{r'} = (g_1^z)^{r'} = (g_1^{r'})^z = (u'_1)^z.$$

Therefore,  $D_1$  returns  $e'/h^{r'}$  from eq.(7). In  $m\mathcal{CS}$ ,

$$h^{r'} = (g_1^{z_1} g_1^{z_2})^{r'} = (g_1^{r'})^{z_1} (g_2^{r'})^{z_2} = (u'_1)^{z_1} (u'_2)^{z_2}.$$

Therefore,  $D_2$  returns  $e'/h^{r'}$  from eq.(18).

Now suppose that  $C$  is invalid, but it is accepted by  $D_1$  and  $D_2$ . If this happens, then  $B_2$  cannot simulate  $D_1$ . Let  $p_{no}$  denote the probability that this occurs. Then similarly to Claim C.1, it holds that

$$p_{no} \leq \epsilon.$$

Hence,

$$\Pr(\tilde{b} = b \text{ in } B_2) \geq \Pr(\tilde{b} = b \text{ in } B_1) - p_{no}.$$

From eq.(3),

$$\begin{aligned} \text{Adv}_{m\mathcal{CS},(p,g_1)}^{\text{s-cca}}(B_2) &\geq \text{Adv}_{\mathcal{CS},(p,g_1)}^{\text{s-cca}}(B_1) - 2p_{no} \\ \text{Adv}_{\mathcal{CS},(p,g_1)}^{\text{s-cca}}(B_1) &\leq \text{Adv}_{m\mathcal{CS},(p,g_1)}^{\text{s-cca}}(B_2) + 2p_{no} \\ &\leq \text{Adv}_{m\mathcal{CS},(p,g_1)}^{\text{s-cca}}(B_2) + 2\epsilon. \end{aligned}$$

Finally, from lemma C.1, we have

$$\text{Adv}_{\mathcal{CS},(p,g_1)}^{\text{s-cca}}(t, q_d) \leq 2 \cdot \text{Adv}_{p,g_1}^{\text{ddh}}(t') + 3\epsilon,$$

where  $t' = t + O(q_d \cdot T^{\text{exp}})$  because the time-complexity of  $B_1$  is the same as that of  $B_2$ .

## D Proof of Lemma 6.1

**Lemma D.1** *Let  $E$  and  $Y$  be two events. If*

$$\Pr(E \mid \neg Y) = 1/2,$$

*then*

$$\Pr(Y) \geq 2\Pr(E) - 1.$$

(Proof)

$$\begin{aligned}
\Pr(E) &= \Pr(E \mid Y) \Pr(Y) + \Pr(E \mid \neg Y) \Pr(\neg Y) \\
&\leq \Pr(Y) + \frac{1}{2}(1 - \Pr(Y)) \\
&= \frac{1}{2} \Pr(Y) + \frac{1}{2}
\end{aligned}$$

Q.E.D.

**Lemma D.2** *Let  $E_1$  and  $E_2$  be two events. Then*

$$\Pr(E_1 \wedge \neg E_2) + \frac{1}{2} \Pr(\neg E_1 \wedge \neg E_2) \geq \frac{1}{2} + \frac{1}{2} \Pr(E_1) - \frac{3}{2} \Pr(E_2).$$

(Proof)

$$\begin{aligned}
\Pr(E_1 \wedge \neg E_2) + \frac{1}{2} \Pr(\neg E_1 \wedge \neg E_2) &\geq \Pr(E_1) - \Pr(E_2) + \frac{1}{2}(\Pr(\neg E_1) - \Pr(E_2)) \\
&= \Pr(E_1) + \frac{1}{2}(1 - \Pr(E_1)) - \frac{3}{2} \Pr(E_2) \\
&= \frac{1}{2} + \frac{1}{2} \Pr(E_1) - \frac{3}{2} \Pr(E_2).
\end{aligned}$$

Q.E.D.

Let  $B$  be a type 0 adversary attacking  $\mathcal{H}^n$  with time-complexity at most  $t'$ . We will design a type 0 adversary  $D_B$  for  $\mathcal{PE}^n$ , where  $D_B$  has time complexity at most  $t''$ .

$B$  behaves as follows. Remember that  $N = \{1, \dots, n\}$  is the set of all recipients.

1.  $B$  sends  $N, M_0$  and  $M_1$  to the encryption oracle of  $\mathcal{H}^n$ .
2. The encryption oracle chooses a random bit  $c$  and gives a challenge ciphertext  $\mathcal{E}_{pk}^n(N, r^*) \parallel M_c \oplus G(r^*)$  to  $B$ , where  $r^*$  is a random element.
3.  $B$  finally outputs  $\tilde{c}$ .

If  $B$  does not query  $r^*$  to the random oracle  $G$ ,  $B$  has no advantage in distinguishing  $M_0$  and  $M_1$ . Therefore,

$$\Pr(c = \tilde{c} \mid r^* \text{ is not queried}) = 1/2.$$

Then from lemma D.1 and eq.(3), we have that

$$\Pr(r^* \text{ is queried}) \geq 2\Pr(c = \tilde{c}) - 1 = \mathbf{AdvTO}_{\mathcal{H}^n, I}^{n\text{-cpa}}(B). \quad (23)$$

Now let the input to  $D_B$  be  $\underline{pk}$ . Then  $D_B$  first gives  $\underline{pk}$  to  $B$ . Next  $D_B$  behaves as follows.

1.  $D_B$  chooses  $r_0$  and  $r_1$  randomly. It sends  $N, (r_0, \dots, r_0)$  and  $(r_1, \dots, r_1)$  to the encryption oracle of  $\mathcal{PE}^n$ .
2. Then the encryption oracle chooses a random bit  $b$  and gives a challenge ciphertext  $Z = \mathcal{E}_{\underline{pk}}^n(N, r_b)$  to  $D_B$ .
3.  $D_B$  chooses a random element  $\alpha$ . It will be used as  $G(r_b) = G(r_{1-b}) = \alpha$ .
4.  $D_B$  runs  $B$  as follows.
  - 4-1. If  $B$  queries  $r \in \{r_0, r_1\}$  to  $G$ , then  $D_B$  returns  $\alpha$  as the value of  $G(r)$ . Otherwise,  $D_B$  simulates the random oracle  $G$  in the natural way. (It flips coins to answer queries and makes a set  $Q = \{r, G(r)\}$ , where  $r$  is the query made by  $B$  and  $G(r)$  is the answer of  $D_B$ .)
  - 4-2. Suppose that  $B$  sends  $N, M_0$  and  $M_1$  to the encryption oracle of  $\mathcal{H}^n$ . Then  $D_B$  chooses a random bit  $c$  and returns a ciphertext of  $M_u$  such that  $Z || M_u \oplus \alpha$  to  $B$ .
5. Suppose that  $B$  stops. Then  $D_B$  outputs  $\tilde{b}$  such that

$$\tilde{b} = \begin{cases} 0 & \text{if } r_0 \in Q \text{ and } r_1 \notin Q \\ 1 & \text{if } r_1 \in Q \text{ and } r_0 \notin Q \\ \text{random} & \text{otherwise} \end{cases}$$

$D_B$  fails to simulate  $G$  if  $B$  queries  $r_{1-b}$ . However,  $B$  has no information on  $r_{1-b}$  through the whole experiment. Therefore, this probability is bounded by

$$\Pr(D_B \text{ fails to simulate}) = \Pr(r_{1-b} \in Q) = q_G/2^l$$

because  $r_{1-b}$  is randomly chosen by  $D_B$ . Hence,

$$\Pr(r_b \in Q) \geq \mathbf{AdvTO}_{\mathcal{H}^n, I}^{n\text{-cpa}}(B) - q_G/2^{l-1}$$

from eq.(23). Now from lemma D.2, we have that

$$\begin{aligned}
\Pr(\tilde{b} = b) &= \Pr(r_b \in Q \text{ and } r_{1-b} \notin Q) + \frac{1}{2} \Pr(r_b \notin Q \text{ and } r_{1-b} \notin Q) \\
&= \frac{1}{2} + \frac{1}{2} \Pr(r_b \in Q) - \frac{3}{2} \Pr(r_{1-b} \in Q) \\
&\geq \frac{1}{2} + \frac{1}{2} \left( \text{AdvTO}_{\mathcal{H}^n, I}^{n\text{-cpa}}(B) - \frac{q_g}{2^l} \right) - \frac{3}{2} \frac{q_G}{2^l} \\
&= \frac{1}{2} + \frac{1}{2} \text{AdvTO}_{\mathcal{H}^n, I}^{n\text{-cpa}}(B) - \frac{q_G}{2^{l-2}}
\end{aligned}$$

Finally, from eq.(3), we obtain that

$$\begin{aligned}
\text{AdvTO}_{\mathcal{PE}^n, I}^{n\text{-cpa}}(D_B) &\geq \text{AdvTO}_{\mathcal{H}^n, I}^{n\text{-cpa}}(B) - \frac{q_G}{2^{l-3}} \\
\text{AdvTO}_{\mathcal{H}^n, I}^{n\text{-cpa}}(B) &\leq \text{AdvTO}_{\mathcal{PE}^n, I}^{n\text{-cpa}}(D_B) + \frac{q_G}{2^{l-3}} \\
\text{AdvTO}_{\mathcal{H}^n, I}^{n\text{-cpa}}(t) &\leq \text{AdvTO}_{\mathcal{PE}^n, I}^{n\text{-cpa}}(t') + \frac{q_G}{2^{l-3}}.
\end{aligned}$$

It is easy to see that  $t'' = t' + O(q_G) + O(n)$ .

## E Proof of Lemma 6.2

Let  $B$  be a type 0 adversary attacking  $\mathcal{HY}^n$  with time-complexity at most  $t'$ . We will design a type 0 adversary  $A_B$  for  $\mathcal{PE}^n$ , where  $A_B$  has time complexity at most  $t''$ .

$B$  behaves as follows. Remember that  $N = \{1, \dots, n\}$  is the set of all recipients.

1.  $B$  sends  $N, M_0$  and  $M_1$  to the encryption oracle of  $\mathcal{HY}^n$ .
2. The encryption oracle chooses a random bit  $u$  and gives a challenge ciphertext  $C_N = c_1 || c_2 || c_3$  to  $B$ , where

$$c_1 = M_u \oplus G(r^*), \quad c_2 = H(r^* || M_u), \quad c_3 = \mathcal{E}_{\underline{pk}}^n(N, \underline{r}^*)$$

and  $r^*$  is a random element.

3.  $B$  finally outputs  $\tilde{u}$ .

Let  $Y$  be the event that  $B$  queries  $r^*$  to the random oracle  $G$  or  $r^*||M$  to the random oracle  $H$  for some  $M$ . Then it is easy to see that  $B$  has no information on  $u$  if  $Y$  does not occur. Therefore,

$$\Pr(\tilde{u} = u \mid \neg Y) = 1/2.$$

Hence from lemma D.1 and eq.(3), we have

$$\Pr(Y) \geq 2\Pr(\tilde{u} = u) - 1 = \mathbf{Adv}_{\mathcal{HY}^n, I}^{n\text{-cca}}(B). \quad (24)$$

Now let the input to  $A_B$  be  $\underline{pk}$ . Then  $A_B$  first gives  $\underline{pk}$  to  $B$ . Next  $A_B$  behaves as follows.

1.  $A_B$  chooses  $r_0$  and  $r_1$  randomly. It sends  $N, (r_0, \dots, r_0)$  and  $(r_1, \dots, r_1)$  to the encryption oracle of  $\mathcal{PE}^n$ .
2. Then the encryption oracle chooses a random bit  $b$  and gives a challenge ciphertext  $Z = \mathcal{E}_{\underline{pk}}^n(N, r_b)$  to  $A_B$ .
3.  $A_B$  chooses two random elements  $\alpha$  and  $\beta$ . They will be used as

$$G(r_b) = G(r_{1-b}) = \alpha, \quad H(r_b||M_u) = H(r_{1-b}||M_u) = \beta.$$

4.  $A_B$  runs  $B$  as follows.

- 4-1. Suppose that  $B$  sends  $N, M_0$  and  $M_1$  to the encryption oracle of  $\mathcal{HY}^n$ . Then  $A_B$  chooses a random bit  $u$  and returns a ciphertext of  $M_u$  such that

$$C_N = M_u \oplus \alpha||\beta||Z$$

to  $B$ .

- 4-2. Suppose that  $r \in \{r_0, r_1\}$ . If  $B$  queries  $r$  to  $G$ , then  $A_B$  returns  $\alpha$  and if  $B$  queries  $r||M_u$  to  $H$ , then  $A_B$  returns  $\beta$ .
- 4-3. Otherwise,  $A_B$  simulates  $G$  and  $H$  in the natural way. That is, it flips coins to answer the queries and makes the sets  $Q_G = \{r, G(r)\}$  and  $Q_H = \{r||M, H(r||M)\}$ .
- 4-4.  $A_B$  simulates the decryption oracles of  $\mathcal{HY}^n$  as follows. Suppose that  $B$  asks  $C' = c'_1||c'_2||c'_3$  to  $D_{sk_i}$ . If  $c'_3 \neq \text{TAKE}_i(Z)$ , then  $A_B$  can ask  $c'_3$  to  $D_{sk_i}$ . Hence,  $A_B$  can decrypt it properly.

If  $c'_3 = \text{TAKE}_i(Z)$ , then  $A_B$  cannot ask  $c'_3$  to  $D_{sk_i}$ . However, we know that  $c'_3$  is a ciphertext of  $r_0$  or  $r_1$  in this case. Therefore, if  $C'$  is a legal ciphertext, then the plaintext must be  $M' \stackrel{\text{def}}{=} c'_1 \oplus \alpha$ . From this observation,  $A_B$  answers as follows.

- (a)  $A_B$  returns  $M'$  to  $B$  if  $r_0 || M' \in Q_H$  and  $c'_2 = H(r_0 || M')$  or if  $r_1 || M' \in Q_H$  and  $c'_2 = H(r_1 || M')$ .
- (b) Otherwise,  $A_B$  returns *reject* to  $B$ .

5. Suppose that  $B$  stops. Let  $Y_0$  be the event that  $r_0 \in Q_G$  or  $r_0 || M \in Q_H$  for some  $M$ . Let  $Y_1$  be the event that  $r_1 \in Q_G$  or  $r_1 || M \in Q_H$  for some  $M$ . Then  $D_B$  outputs  $\tilde{b}$  such that

$$\tilde{b} = \begin{cases} 0 & \text{if } Y_0 \text{ occurs and } Y_1 \text{ does not occur} \\ 1 & \text{if } Y_1 \text{ occurs and } Y_0 \text{ does not occur} \\ \text{random} & \text{otherwise} \end{cases}$$

$A_B$  fails to simulate the real world if

- 1.  $Y_{1-b}$  occurs.
- 2. At step 4-3 (b),  $A_B$  returns *reject* for a legal ciphertext queried by  $B$ .

Note that  $B$  has no information on  $r_{1-b}$  since  $r_{1-b}$  is randomly chosen by  $A_B$ . Therefore, it holds that

$$\Pr(Y_{1-b} \text{ occurs}) = (q_G + q_H)/2^l.$$

Further,  $B$  makes at most  $nq_d$  queries in total to the decryption oracles. Hence, we have that

$$p_f \stackrel{\text{def}}{=} \Pr(A_B \text{ fails to simulate the real world}) \leq \frac{q_G + q_H}{2^l} + \frac{nq_d}{2^h}.$$

Then from eq.(24), we obtain that

$$\Pr(Y_b \text{ occurs}) \geq \text{Adv}_{\mathcal{HY}^n, I}^{n\text{-cca}}(B) - p_f.$$

Now from lemma D.2, we have that

$$\Pr(\tilde{b} = b) \geq \Pr(Y_b \text{ and } \neg Y_{1-b}) + \frac{1}{2} \Pr(\neg Y_b \text{ and } \neg Y_{1-b})$$

$$\begin{aligned}
&= \frac{1}{2} + \frac{1}{2} \Pr(Y_b) - \frac{3}{2} \Pr(Y_{1-b}) \\
&\geq \frac{1}{2} + \frac{1}{2} (\text{Adv}_{\mathcal{HY}^n, I}^{n\text{-cca}}(B) - p_f) - \frac{3}{2} \frac{q_G + q_H}{2^l} \\
&= \frac{1}{2} + \frac{1}{2} (\text{Adv}_{\mathcal{HY}^n, I}^{n\text{-cca}}(B) - \sigma),
\end{aligned}$$

where

$$\sigma = p_f + 3 \frac{q_G + q_H}{2^l} = \frac{q_G + q_H}{2^{l-2}} + \frac{nq_d}{2^h}$$

From eq.(3), we obtain that

$$\begin{aligned}
\text{Adv}_{\mathcal{PE}^n, I}^{n\text{-cca}}(A_B) &\geq (\text{Adv}_{\mathcal{HY}^n, I}^{n\text{-cca}}(B) - \sigma) \\
\text{Adv}_{\mathcal{HY}^n, I}^{n\text{-cca}}(B) &\leq \text{Adv}_{\mathcal{PE}^n, I}^{n\text{-cca}}(A_B) + \sigma,
\end{aligned}$$

Therefore,

$$\begin{aligned}
\text{Adv}_{\mathcal{HY}^n, I}^{n\text{-cca}}(B) &\leq \text{Adv}_{\mathcal{PE}^n, I}^{n\text{-cca}}(A_B) + \sigma \\
\text{AdvTO}_{\mathcal{HY}^n, I}^{n\text{-cca}}(t, q_d) &\leq \text{AdvTO}_{\mathcal{PE}^n, I}^{n\text{-cca}}(t', q_d) + \sigma,
\end{aligned}$$

It is easy to see that  $t'' = t' + O(q_G) + O(q_H) + O(q_d) + O(n)$ .
